**Abstract**—Low Density Parity Check(LDPC) code is an efficient way of communication and is being largely used in mobile communication. With the wide usage and having computational intensity of LDPC decoders, there has been a lot of effort to reduce decoder's complexity and parallel implementation of it. On the other hand, recent improvements in mobile processors's architectures has made it exclusively reachable to have a real-time decoder based on a software solution. Knowing this capability, low profile GPU based decoders has been introduced that are capable of reaching high throughput by low latency. On the other hand recently there has been some work that has used ARM SIMD and SIMT programming models instead of GPU that promises satisfying quality. What this works miss is that a mobile processor that is used in a smart phone should support a lot of task and we can not allocate all resources to decoding processes. In this paper we propose a heterogeneous LDPC decoder that uses both ARM and GPU Processors of a mobile device to reach real-time efficiency. The different stages of decoder processes has been allocated to ARM and GPU based on an optimization solution.

## I. INTRODUCTION

Originally proposed by Robert Gallager in 1962 [1] and rediscovered by MacKay and Neal in 1996 [2] Low Density Parity Check (LDPC) codes have been adopted by a wide range of applications including many communication system standards such as WiFi(IEEE 802.11n), 10 Gbit Ethernet (IEEE 802.3an), WiMAX (IEEE 802.16e), and DVB-S2. Recently, Chung and Richardson [3] showed that the LDPC code can approach the Shannon limit to within 0.0045 dB. However, the drawback of high correcting efficiency comes from its decoding computation complexity [4] and to date there exist no known mathematical tools to accurately evaluate their performance. Thus, a resort is typically made to simulations using computers or dedicated hardware [5].

LDPC decoding algorithms are compute-intensive and need powerful computer architecture to convey low latency and high decoding rate which caused to be initially implemented using application-specific integrated circuits(ASIC) and field-programmable gate array(FPGA) circuits [6]. However, their high speed often comes at a price of high development cost and low programming flexibility [7] and it is very challenging to design decoder hardware that supports various standards and multiple data rates [8]. On the other hand, iterative LDPC decoding schemes based on the sum-product algorithm (SPA)

can fully be parallelized, leading to high-speed decoding [3]. For these reasons, designers have recently focused on software implementations of LDPC decoders on multi/many-core devices [9] to achieve requirements through Software Defined Radio (SDR) Systems.

As in terms of multicore architectures, researchers have used CPUs [10], [11], GPUs [5], [9], [12] and ARM [11], [13] architectures to develop high throughput, low latency SDR systems.

In microarchitectures, increasing clock frequencies to obtain performance has reached a limit, so to hold this increase, other techniques based on parallel processing is being investigated [4]. Today's multicore architectures support SIMD (Single Instruction Multiple Data), SPMD(Single Program Multiple Data) and SIMT(Single Instruction Multiple Threads). The general purpose multicore processors replicate a single core in a homogeneous way, typically with a x86 instruction set, and provide shared memory hardware mechanisms [9]. They can be programmed at a high level by using different software technologies [14]. OpenMP [15] provides an effective and relatively straightforward approach for programming general-purpose multicores. On the other hand newer microarchitectures are trying to provide larger SIMD units for vector processing like SSE, AVX and AVX2 [16] on Intel Architectures. In [4], the authors have used Intel SSE/AVX2 SIMD Units to efficiently implement a high throughput LDPC decoder. In [8], OpenMp is used to generate address patterns with parity check H-matrix.

Mainly due to the demands for visualization technology in the games industry, the performance of graphics processing units (GPUs) has undergone increasing performances over the last decade. With many cores driven by a considerable memory bandwidth, recent GPUs are targeted for computationally intensive, multithreaded, highly parallel computation, and researchers in high-performance computing fields are applying GPUs to general-purpose applications (GPGPU) [5], [8], [12], [17]–[19]. They have used Compute Unified Device Architecture (CUDA) from NVIDIA [20] and Open Computing Language (OpenCL) platforms to develop LDPC Decoders.

Due to large computing capacity of multicore devices, software LDPC decoders have met the required throughputs of communication standards, although power consumption of x86

and GPU devices is incompatible with most of the embedded systems [13]. To solve this issue, ARM-based SDR systems have been proposed in recent years [6], [11], [13] with goal of a SDR LDPC decoder that provides high throughput, low latency on a low-power embedded system. The authors in [13] have used ARM Processors's NEON SIMD and SIMD programming models to implement a horizontal layered-based decoder that is based on parallel decoding of a low set of frames. This approach allows reaching high throughput while maintaining low-latency. Due to restrictions in an embedded system, using all resources of the system is a crucial task. Recent works in SDR LDPC embedded systems are missing the fact that today's mobile devices have powerful CUDA enabled GPUs. This paper has proposed a new algorithm that exploits ARM NEON SIMD Units and GPU together to reach a high throughput, low latency LDPC decoder. The main specification of the algorithm is that it divides processing task between system's resources.

## II. LDPC CODES AND THEIR DECODING PROCESSES

### III. PARALLEL FRAME PROCESSING

### IV. RESULTS

### V. CONCLUSION

The conclusion goes here.
